Graphs

Figure: A graph G

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ □ のへぐ

- Vertices or nodes (denoted by V(G))
- ► Edges (denoted by *E*(*G*))

Subgraphs

A subgraph of a graph G is a graph H, where $V(H) \subseteq V(G)$ and $E(H) \subseteq E(G)$.

An induced subgraph of a graph G is a subgraph H obtained from G by deleting some vertices of G. (We say that G contains H.)

Figure: A graph, an induced subgraph, and a non-induced subgraph

Graphs closed under taking induced subgraphs

Hereditary property is a graph property which holds for a graph and is inherited by all its *induced* subgraphs.

Example

A class of graphs that do not contain a clique on 3 vertices is hereditary.

Definition

A class of graphs is hereditary if it is **closed** under taking induced subgraphs. (Closed means that if a graph G is in class C, then for every induced subgraph H of G, the graph H is also in C.)

Hereditary class of graphs

Any hereditary class can be characterized as the class of graphs that **do not contain (or exclude)** any graph in some family \mathcal{F} .

• forests =
$$(C_3, C_4, C_5, C_6, C_7, ...)$$
-free

- bipartite graphs = (C_3, C_5, C_7, \dots) -free
- chordal graphs = $(C_4, C_5, C_6, C_7, \dots)$ -free
- perfect graphs = $(C_3, \overline{C_3}, C_5, \overline{C_5}, C_7, \overline{C_7}, \dots)$ -free
- P₄-free graphs, (P₄, C₄)-free graphs, etc...

G is *F*-free if no induced subgraph of *G* is isomorphic to *F*; and is \mathcal{F} -free if no induced subgraph of *G* is isomorphic to each $F \in \mathcal{F}$.

Remark: \mathcal{F} can be a finite/infinite family.

(Possibly) naive answers...

There are many possibilities to forbid induced subgraphs, so this could lead to publishing many papers.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

(Possibly) naive answers...

There are many possibilities to forbid induced subgraphs, so this could lead to publishing many papers.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

In real world, many problems can be formulated as graphs, where:

- vertices represent objects;
- edges represent constraints.

Note:

Removing object is equivalent to removing vertex, which means taking an induced subgraph.

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

Main concerns:

- How classes of graphs closed under taking induced subgraphs can be described in the most general possible way?
- What properties can be proved about them?
- Are combinatorial problems such as coloring, maximum independent set polynomial-time solvable?

Note:

Many NP-Hard problems (e.g. coloring, maximum independent set) become easy when some configurations are forbidden. (e.g. forests, chordal graphs, perfect graphs).

Graph Decomposition

Decomposition of graph (*in general*)

A decomposition of a *connected* graph G is a set of **edge-disjoint** subgraphs (*not necessarily induced*) of G, say: H_1, H_2, \ldots, H_n , such that

$$\bigcup_{i} H_i = G$$

The edge-disjoint property implies $\forall i, j, E(H_i) \cap E(H_j) = \emptyset$.

Figure: Decomposition and non-decomposition of a graph

◆□▶ ◆□▶ ◆目▶ ◆目▶ ▲□ ◆ ��や

Decomposition of graph

Figure: Cycle decomposition

Figure: Path decomposition

Another kind of decomposition

A graph can be decomposed in **many ways** and using **many kinds** of decomposition, depending on how we want to use the decomposition theorem to prove graph properties.

For instance, one can consider that the *edge set* used to decompose the graph is contained in each connected components of the graph.

Example:

Figure: Decomposition in which the connected components both contains edge $\{a, e\}$

In this case, what we care about is the vertex set that is used to decompose G. Such a vertex set is called cutset of the graph.

Cutset

Let G be a connected graph. A set of vertices $C \subseteq V(G)$ is called a cutset of G if the removal of C from G disconnects G, i.e. $V(G) \setminus C$ induces a disconnected graph.

Figure: $\{a, e\}$ is a cutset of graph *G* that disconnects the graph into two connected components.

Blocks of decomposition

Let G be a graph, C be a cutset in G, and Q be a component of $G \setminus C$. The graph induced by $V(Q) \cup V(C)$ is called a block of decomposition of $G \setminus C$.

Figure: Blocks of decomposition

Decomposition theorem for a class of graphs

Definition (Decomposition theorem in general...)

A decomposition theorem for a class ${\mathcal C}$ says that every object of ${\mathcal C}$ either:

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

- belongs to some well-understood basic class; or
- it can be broken into smaller pieces according to some well-described rules.

Decomposition theorem for a class of graphs

More formally, for a class of graphs C, we define a set of basic graphs C_0 and a list of graph *decomposition* operations \mathcal{L} , s.t. if $G \in C$:

▶ either $G \in C_0$; or

► G can be broken down to smaller graphs G' and G'' using an operation in L (here we usually use the so-called *cutset*).

Note:

If furthermore, every G can be built from smaller graphs G' and G'' belonging to C using a compositions operation \mathcal{L}' (the "reverse" operations of \mathcal{L} , then it is a structure theorem).

Example of decomposition

 $C \subsetneq V(G)$ is a clique cutset of a connected graph G if C is a cutset of G and C induces a complete graph.

Clique cutset decomposition (Tarjan, 1985)

Example of decomposition theorem

Figure: Decomposition theorem

How decomposition is used for algorithms

The graph-decomposition based algorithm is usually done through the divide-and-conquer approach.

Figure: Illustration of divide-and-conquer algorithm

How decomposition is used for graph recognition?

Given a class of graphs \mathcal{C} . How do we decide if a given input graph G is in \mathcal{C} ?

- Get a decomposition theorem of C (the decomposition must be *class-preserving*);
- 2. Decompose G until no decomposition is possible;
- 3. Check if all graphs obtained from the decomposition are basic graphs of \mathcal{C} .

How decomposition is used for combinatorial problem

- Vertex coloring: assignment of (as minimum possible) colors to the vertices, no adjacent vertices receive the same color
- Maximum independent set: finding set of pairwise non-adjacent vertices with maximum cardinality
- Maximum clique: finding set of pairwise adjacent vertices with maximum cardinality

 $\begin{array}{c} {\rm coloring} \\ {\rm chromatic\ number\ :\ } \chi \end{array}$

max independent set independent set number: α

 $\begin{array}{c} {\rm maximum\ clique}\\ {\rm clique\ number\ :\ } \omega \end{array}$

Structure of triangle-free even-hole-free graphs

Part 1 Decomposition theorem of triangle-free even-hole-free (tf-ehf) graphs

Reference: Triangle-Free Graphs Signable without Even Holes [2]

chordless cycle $(hole \text{ if it has length} \ge 4)$

A graph is even-hole-free if it does not contain an even hole as an induced subgraph.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

What is triangle?

Triangle is the complete graph of three vertices.

Triangle-free even-hole-free graphs are graphs that do not contain an *even-hole* and a *triangle* as an induced subgraph.

Forbidden structure in tf-ehf graphs

Figure: Truemper configurations; dashed lines represent paths of length at least $1 \label{eq:stable}$

Every triangle-free even-hole-free graph is (theta, prism, pyramid, even wheel)-free *.

C: the class of (triangle, theta, even wheel)-free graphs

^{*}even wheel is a wheel with an even number of spokes $\langle \neg \rangle$, \langle

Decomposition theorem of tf-ehf graphs

Theorem (Decomposition of triangle-free ehf graphs [2)] For any graph $G \in C^{\dagger}$, one of the following holds.

- G is either a K_1 , K_2 , a hole, or the cube.
- ► G has a clique cutset.
- G contains a wheel, and it can be decomposed with any arbitrarily chosen wheel.

Assumption: along the proof, we assume that the studied graph is connected.

 $^{^{\}dagger}\mathcal{C}$ is the class of (triangle, theta, even wheel)-free graphs $\rightarrow 4 \equiv 4 = 2$

Sketch of decomposition of tf-ehf graphs

Wheel decomposition

Sketch of decomposition of tf-ehf graphs

Wheel decomposition

Sketch of proof (1): Study clique cutset on the graph

Remark

Let $G \in C$. Since G is triangle free, the only clique cutset that may exists in G is K_1 or K_2 .

Lemma (Clique cutset lemma)

If G has a clique cutset, then G is (theta, prism, pyramid)-free if and only if all blocks of the clique cutset decomposition are (theta, prism, pyramid)-free.

Implication: we may assume that our graph G does not have a clique cutset.

Proof of clique cutset lemma

- Let G be a (theta, prism, pyramid)-free graph, and C be a clique cutset in G.
- For a contradiction, suppose that there exists a block of decomposition Q containing a theta T.
- Since G is theta-free, then T must contains vertices of Q and $G \setminus Q$.
- Study how the vertices of T are positioned in Q and G \ Q. This will lead to a contradiction.
- Apply a similar analysis, by assuming G contains a prism or a pyramid.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Sketch of proof (2): Study attachment on cube

Lemma

Let $G \in C$ be a graph containing no K_1 or K_2 cutset. If G contains a cube, then G itself is a cube.

Sketch of proof.

- ► Assume that G contains cube M.
- Study the attachment of vertices in $G \setminus M$ into M.
 - Study what happens if all vertices in G \ M has no neighbor in M.
 - Study what happens if a vertex x ∈ G \ M has ≥ 2 neighbors in M.
 - Study what happens if all vertices in G \ M have at most one neighbor in M.

Implication: we may assume that G does not have a clique cutset and the cube (i.e., $(K_1, K_2, \text{ cube})$ -free).

Sketch of proof (3): Study attachment on hole Lemma (Hole attachment lemma) Let $G \in C$ that contains no clique cutset, H be a hole in G. Then either: G = H:

► G contains a wheel (H, v);

• G contains a wheel (H', y) as shown in the following figure.

Sketch of proof (4): Wheel decomposition

Let G be a connected triangle-free graph that contains a wheel (H, v). Let v_1, \ldots, v_n be the neighbors of v in H appearing in this order when traversing H. Then G can be decomposed with a wheel (H, v) if the following holds:

- 1. $G \setminus \{v, v_1, \dots, v_n\}$ contains exactly *n* connected components: Q_1, \dots, Q_n .
- 2. The intermediate nodes of the sector with endnodes v_i and v_{i+1} belong to Q_i , and no node of Q_i is adjacent to v_j , $j \neq i, i + 1$.

Lemma (Wheel decomposition)

Let G be a (triangle, theta, even wheel)-free graph, and G is not a K_1 , K_2 , a hole, the cube, and G does not contain a clique cutset. Let W be a wheel in G. Then G can be decomposed by W.

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

Wheel decomposition

Lemma (Wheel decomposition)

Let G be a (triangle, theta, even wheel)-free graph, and G is not a K_1 , K_2 , a hole, the cube, and G does not contain a clique cutset. Let W be a wheel in G. Then G can be decomposed by W.

Wheel decomposition

Properties of wheel decomposition

▶ Let (H, v) be a wheel that decompose G, and $v_i, v_j \in N_H(v)$. Then $\{v, v_i, v_j\}$ contains exactly two connected components.

Wheel decomposition (H, v) where $N_H(v) = \{v_1, \ldots, v_n\}$ contains n connected components.

- Every wheel in G is not "decomposed" (i.e. if W is a wheel in G, then W is contained in a block Q_i of the decomposition).
- ▶ If *G* has no clique-cutset, then every block has no clique cutset.
- ▶ If $G \in C$, then every block $Q_i \in C$.

Sketch of proof (5): After wheel decomposition

The wheel decomposition can be applied to each block of decomposition which is not a basic graph. This can be done untul in the end, no block of decomposition contains a wheel (i.e. they are all basic graphs).

This follows from the "hole attachment lemma", that says that when each block $Q \in C$ does not contain any more wheel, then the block of decomposition is a hole.

This proves the "Decomposition Theorem".

Ear

Let *H* be a hole. A chordless path $P = x \dots z$ is an ear of the hole *H* if:

- the intermediate nodes of P are in $V(G) \setminus V(H)$;
- x and z have a common neighbor y in H;
- $(V(H) \setminus \{y\}) \cup V(P)$ induces a hole.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ●の00

Theorem

Let G be a graph that is triangle-free, not the cube, and containing no K_1 and K_2 cutsets and no cube. Then G is (theta, prism, pyramid)-free if and only if it can be obtained:

- starting from a hole;
- doing a sequence of good ear-addition.

Applications of the decomposition/structure theorems

We will discuss:

- 1. The use of decomposition theorem for recognizing if a graph is triangle-free even-hole-free.
- 2. The use of structure theorem for solving combinatorial problems, such as coloring and maximum independent set, through the study of *treewidth*.

Recognizing if a graph in in $\ensuremath{\mathcal{C}}$

Input: A connected *triangle-free* graph G**Output:** YES if G is (theta, prism, pyramid)-free, NO otherwise.

 $\ensuremath{\mathcal{L}}$ is the set of blocks

- Step 1: If G has a K₁-cutset or K₂-cutset, set L = {G}. Otherwise, decompose it with K₁-cutset or K₂-cutset, until it is not decomposable anymore. Let L be the set of blocks.
- 2. Step 2: If every graph in \mathcal{L} has one or two nodes, is a hole or a cube, return YES. Otherwise, go to Step 3.
- Step 3: Study every graph in L that has more than two nodes, but neither a hole nor a cube. Study if the graph can be decomposed with a wheel. Return NO if a graph is not basic and cannot be decomposed by a wheel.
- 4. Repeat Step 2, then Step 3 for every graph that is not *basic*.

Application of the decomposition/structure theorems

Treewidth (intuitively)

Tree decomposition

Tree decomposition of G: "gluing" the pieces of subgraphs of G in a tree-like fashion

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

- width of T = the size of the largest bag 1
- treewidth of G: the minimum over the width of tree decomposition of G

Why treewidth is *algorithmic-ally* powerful?

Theorem (Courcelle, 1990)

Every graph property definable in the monadic second-order logic (MSO) formulas can be decided in linear time on class of graphs of bounded treewidth.

Some graph problems expressible in MSO:

- most combinatorial problems,
- such as: maximum independent set, maximum clique, coloring

▲□▶ ▲□▶ ▲□▶ ▲□▶ ■ ● ●

Treewidth of tf-ehf graphs

```
Theorem (3)
Let G be a triangle-free even-hole-free graph, then the treewidth of G is at most 5.
```

Sketch of proof.

The treewidth of a graph can be computed by applying the following properties.

Lemma

If G is a graph that is contained in a **chordal** graph H as a subgraph, then the treewidth of G is at most one less than the size of the maximum clique of G

Sketch of proof (continue).

- By the structure theorem, any graph G ∈ C can be formed starting from a hole and sequentially adding *ear-attachment*.
- Then, we can add edges to make the graph chordal.
- It can be proved that the size of the maximum clique of the chordal graph is at most 6.

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

Hence the treewidth is at most 5.

Sketch of proof (continue).

Figure: Sketch of *chordalization* of a graph $G \in cC$

▲□▶▲□▶▲≡▶▲≡▶ ≡ めぬる

Most combinatorial problems on tf-ehf graphs are polynomial

Implication of treewidth

Since the treewidth is small, then by Courcelle's theorem, many combinatorial problems are poly-time solvable., such as:

▲ロ ▶ ▲周 ▶ ▲ 国 ▶ ▲ 国 ▶ ● の Q @

- graph coloring; or
- maximum independent set

This is the end of the presentation

▲□▶ ▲□▶ ▲三▶ ▲三▶ 三三 のへで
